

Jellyfish: Networking Data Centers Randomly

Speaker: Chi-Yao Hong, UIUC

Ankit Singla
UIUC

Lucian Popa
HP Labs

Brighten Godfrey
UIUC

“It is anticipated that the whole of the populous parts of the United States will, within two or three years, be covered with network like a spider's web.”

— *The London Anecdotes*,
1848

We have opportunity to build
topologies with great deal more freedom

Two goals

High
throughput

Eliminate bottlenecks
Agile placement of VMs

Incremental
expansion

Easily add/replace
servers & switches

Incremental expansion

Facebook “adding capacity on a daily basis”

Commercial products

- SGI Ice Cube (“Expandable Modular Data Center”)
- HP EcoPod (“Pay-as-you-grow”)

You can add servers, but what about the network?

Today's structured networks

[Al-Fares, Loukissas,
Vahdat; SIGCOMM'08]

Structure constrains expansion

Coarse design points

- Hypercube: 2^k switches
- 3-level fat tree: $5k^2/4$ switches

3-level fat trees, commodity switches:

- 24-port switch → 3,456 servers
- 32-port switch → 8,192 servers
- 48-port switch → 27,648 servers

Workarounds exist, but unclear how to maintain structure incrementally

- Overutilize network? Uneven / constrained bandwidth
- Leave ports free for later? Wasted investment

Our solution

Forget about structure –
let's have **no structure at all!**

Jellyfish

Jellyfish: The topology

Randomly selected
from all valid graphs

Switches are nodes

Capacity as a fluid

Jellyfish random graph

432 servers, 180 switches, degree 12

Capacity as a fluid

Jellyfish random graph

432 servers, 180 switches, degree 12

Jellyfish

Arctapodema
(<http://goo.gl/KoAC3>)

Construction & Expansion

Building Jellyfish

Same procedure for graph construction and incremental expansion

Quantifying expandability

LEGUP: [Curtis, Keshav, Lopez-Ortiz, CoNEXT'10]

Two goals

High throughput

Incremental
expansion

Throughput: Jellyfish vs. Fat tree

Packet level simulation; random permutation traffic

Suspicious?

Intuition: Why Jellyfish works?

- ... and can we do better?

From theory to systems

- Routing?
- Congestion Control?
- Cabling?
- Failure Resilience?

Intuition

If we **fully utilize** all available capacity ...

$$\sum_{\forall \text{links}} \text{capacity}(\text{link})$$

$$\begin{aligned} \text{Number of flows at full throughput (1 Gbps)} &= \frac{\text{total network capacity}}{\text{capacity used per flow}} \\ &= 1 \text{ Gbps} \cdot \text{mean path length} \end{aligned}$$

Mission:
minimize average path length

Example

Fat tree

432 servers, 180 switches, degree 12

Jellyfish random graph

432 servers, 180 switches, degree 12

Example

Fat tree

16 servers, 20 switches, degree 4

Jellyfish random graph

16 servers, 20 switches, degree 4

Example: Fat-tree

Fat-tree:
3 of 15
in < 6 hops

Example: Fat-tree

Fat-tree:
3 of 15
in < 6 hops

Jellyfish has smaller path length

Fat-tree:
3 of 15
in < 6 hops

Jellyfish:
11 of 15
in < 6 hops

Can we do even better?

What's the maximum number of nodes in any graph with **degree 3** and **diameter 2**?

Petersen graph

Degree-diameter bounded graph

Largest known graph size with degree δ and diameter d , June 2010

Degree-diameter vs. Jellyfish

D-D graphs do have
high throughput

Jellyfish within 9%!

What we know so far

flexible, expandable

high throughput

OK, but ...

Routing and
congestion control

Cabling

Intuition

If

we fully utilize all available capacity ...

$$\text{Number of flows at 1 Gbps rate} = \frac{\text{total capacity}}{\text{used capacity per flow}}$$

How to effectively utilize capacity without structure?

Routing and congestion control

[Mudigonda, Yalagandula, Al-Fares, Mogul; NSDI'10]

Congestion
Control

TCP
Multipath TCP

[Wischik, Raiciu, Greenhalgh, Handley; NSDI'11]
and SIGCOMM'11 and NSDI'12

Throughput: Jellyfish vs. Fat tree

Packet level simulation; random permutation traffic

Cabling

~20% fewer switch-to-switch cables

For same # servers as fat tree

Optimization

Place switches centrally

Aggregate bundles

switches

server rack

cluster

Long optical cable: cost += ~\$200

Idea: localize a fraction of connections

Result: Jellyfish retains almost all its gains after matching the same # short and long cables as the fat-tree

Conclusion

High throughput

Expandability

Backup: Throughput under link failures

Backup: Jellyfish has short paths

[686 servers, equal-equipment comparison]

Backup: ECMP does not use enough Jellyfish's path diversity

Backup: Jellyfish provides good fairness

Backup: Simple protocol works
