# Agenda

- Brief introduction to Baidu
- Heterogenous services and their challenges to our SREs
- Anomaly detection in typical services
- ARK : A generalized intelligent operation platform for Baidu services

# Introduction to Baidu

- One the largest search engines in the world
    - ✓ Web/Image/Video/News/...
  - Besides search, we also have
    - ✓ Location Based Service - Maps
    - ✓ Social/Knowledge - Tieba/Zhidao
    - ✓ Online to Offline - Nuomi/Waimai
    - ✓ Finance/Payment - Wallet
    - ✓ Cloud computing - Cloud
  - Covers more than 1 Billion users in total
- 

# Anomaly Detection in Heterogenous Services

- Anomaly Detection in theory

- However, here are some realities

# Divide and Conquer

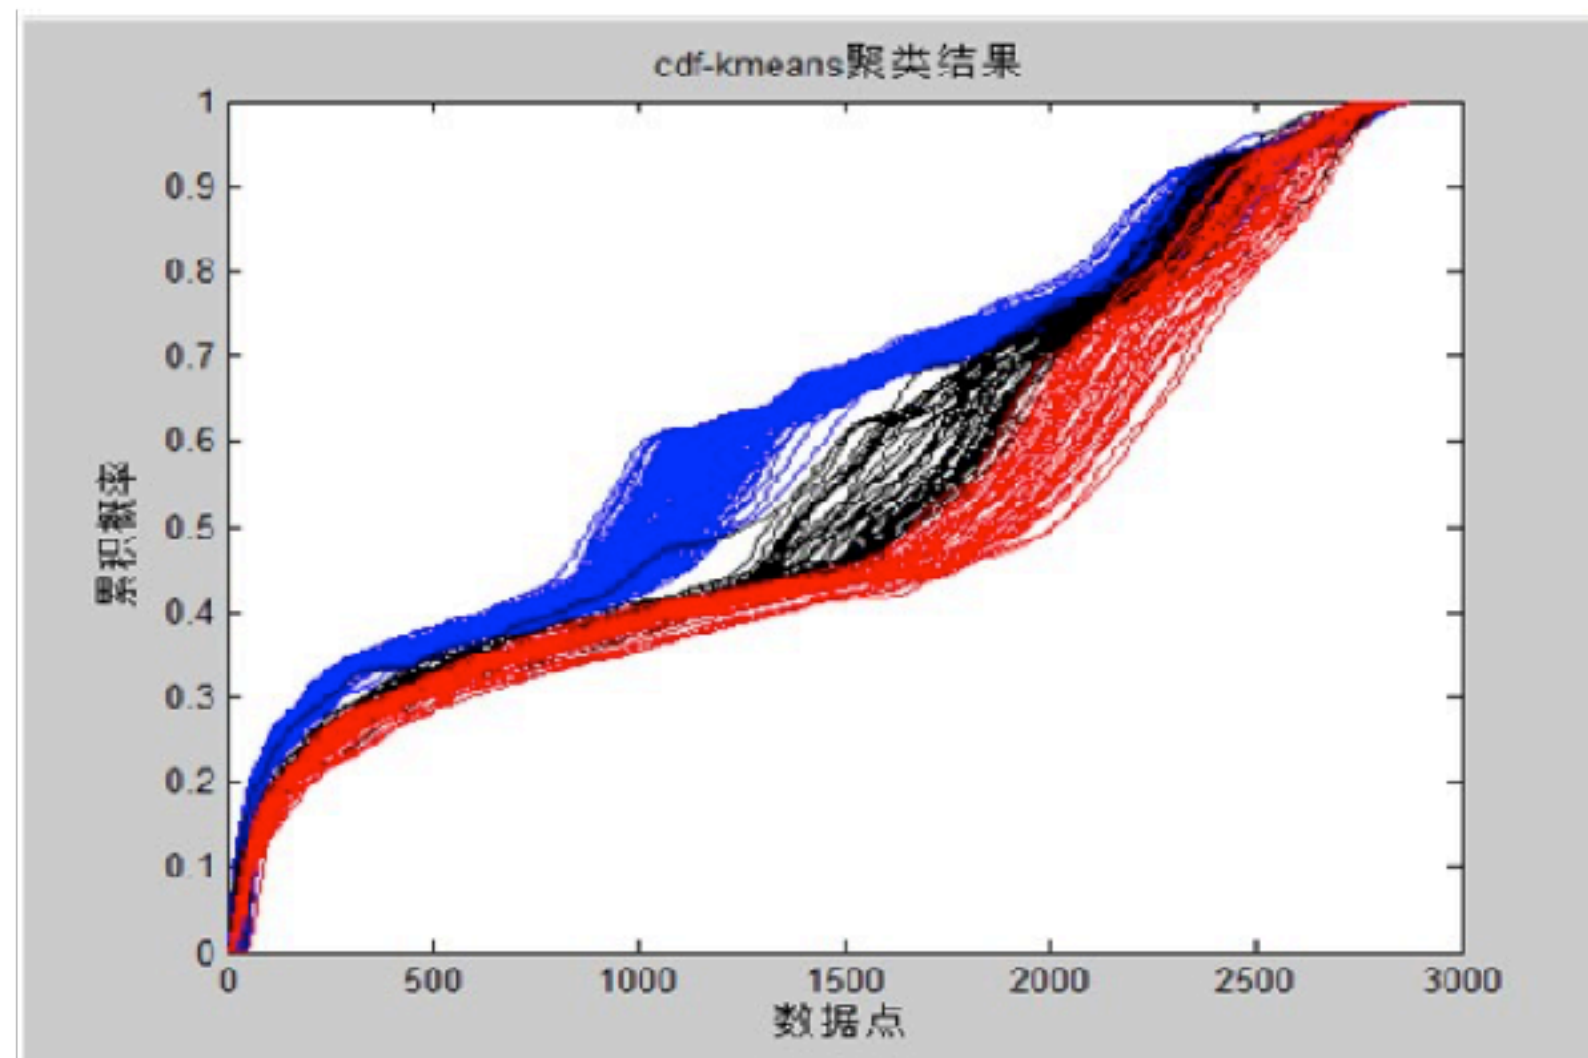

- Several typical categories we manually touch on
  - ✓ Holiday sensitive
  - ✓ Very unstable
  - ✓ Requiring fully automatic configuration

# Holiday Sensitive Curves

- Holidays in Chinese Calendar have no fixed dates
  - ✓ 2016 - Spring Festival (Feb., 8th) - Dragon Boat festival (Jun., 9th)
  - ✓ 2017 - Spring Festival (Jan., 28th) - Dragon Boat festival (May, 30th)
- There is no common pattern among different holidays
- It's hard to know the baselines!
  - ✓ The training data are pretty sparse

# Basic idea and the result

- Clustering on daily CDF of curves
- Classification on dates (features include weekend, holiday, etc.)
- LR based estimated algorithm

# Very Unstable Curves

- Very unstable but not anomaly, caused by
  - ✓ Revenue with significantly different price goods
  - ✓ Revenue under some promotions
- The curve's variance is huge, traditional method cannot guarantee the precision/recall

# Basic Idea and Result

- A compound solution, including
  - ✓ smoothing by sliding window
  - ✓ Reduce the impact from huge absolute values by using logarithm
  - ✓ Considering the increasing/decreasing rate
- The results

# Curves requiring automatic configuration

- Two many curves to monitor, but
  - ✓ No enough bandwidth to do manual configuration from SRE side
  - ✓ Hard to select algorithms
  - ✓ Even harder to setup/adjust parameters
- The examples of such metrics
  - ✓ RPC numbers between two modules
  - ✓ Network transmission amount on some switch devices

# Basic Idea and Results

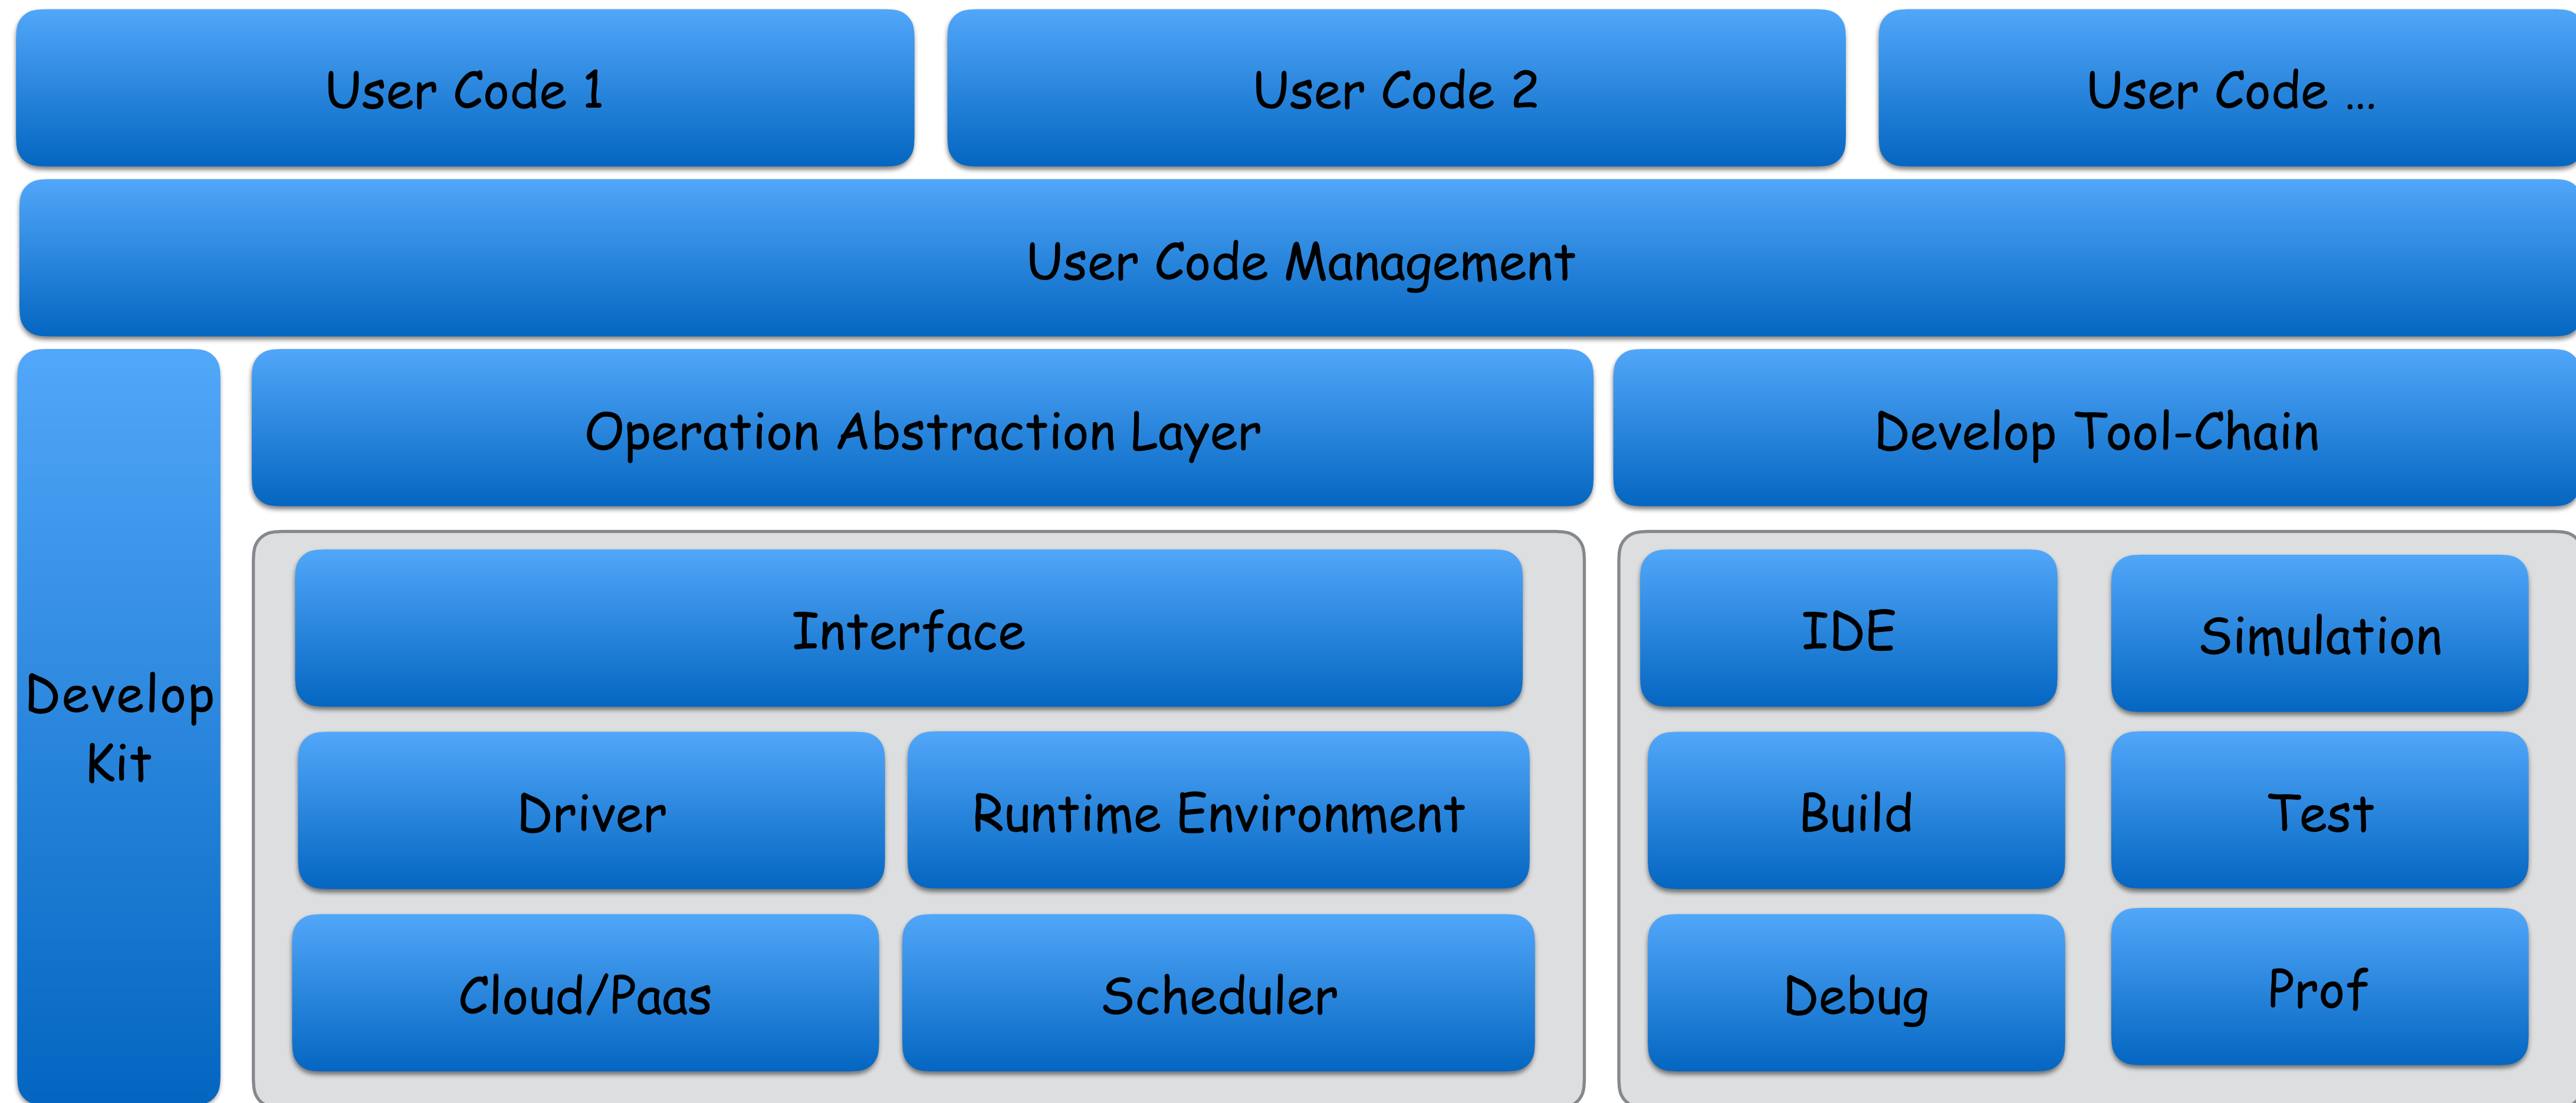

- Using machine learning to select algorithm
  - ✓ Whether or not the curve is periodical
  - ✓ How the curve's stability look like
  - ✓ The difference between maximum and minimum
- The default parameters configuration, plus auto-adjustment based on user feedback (marked by on-call)
- The sampling results so far
  - ✓ Precision is about 84%

# More Pain Points

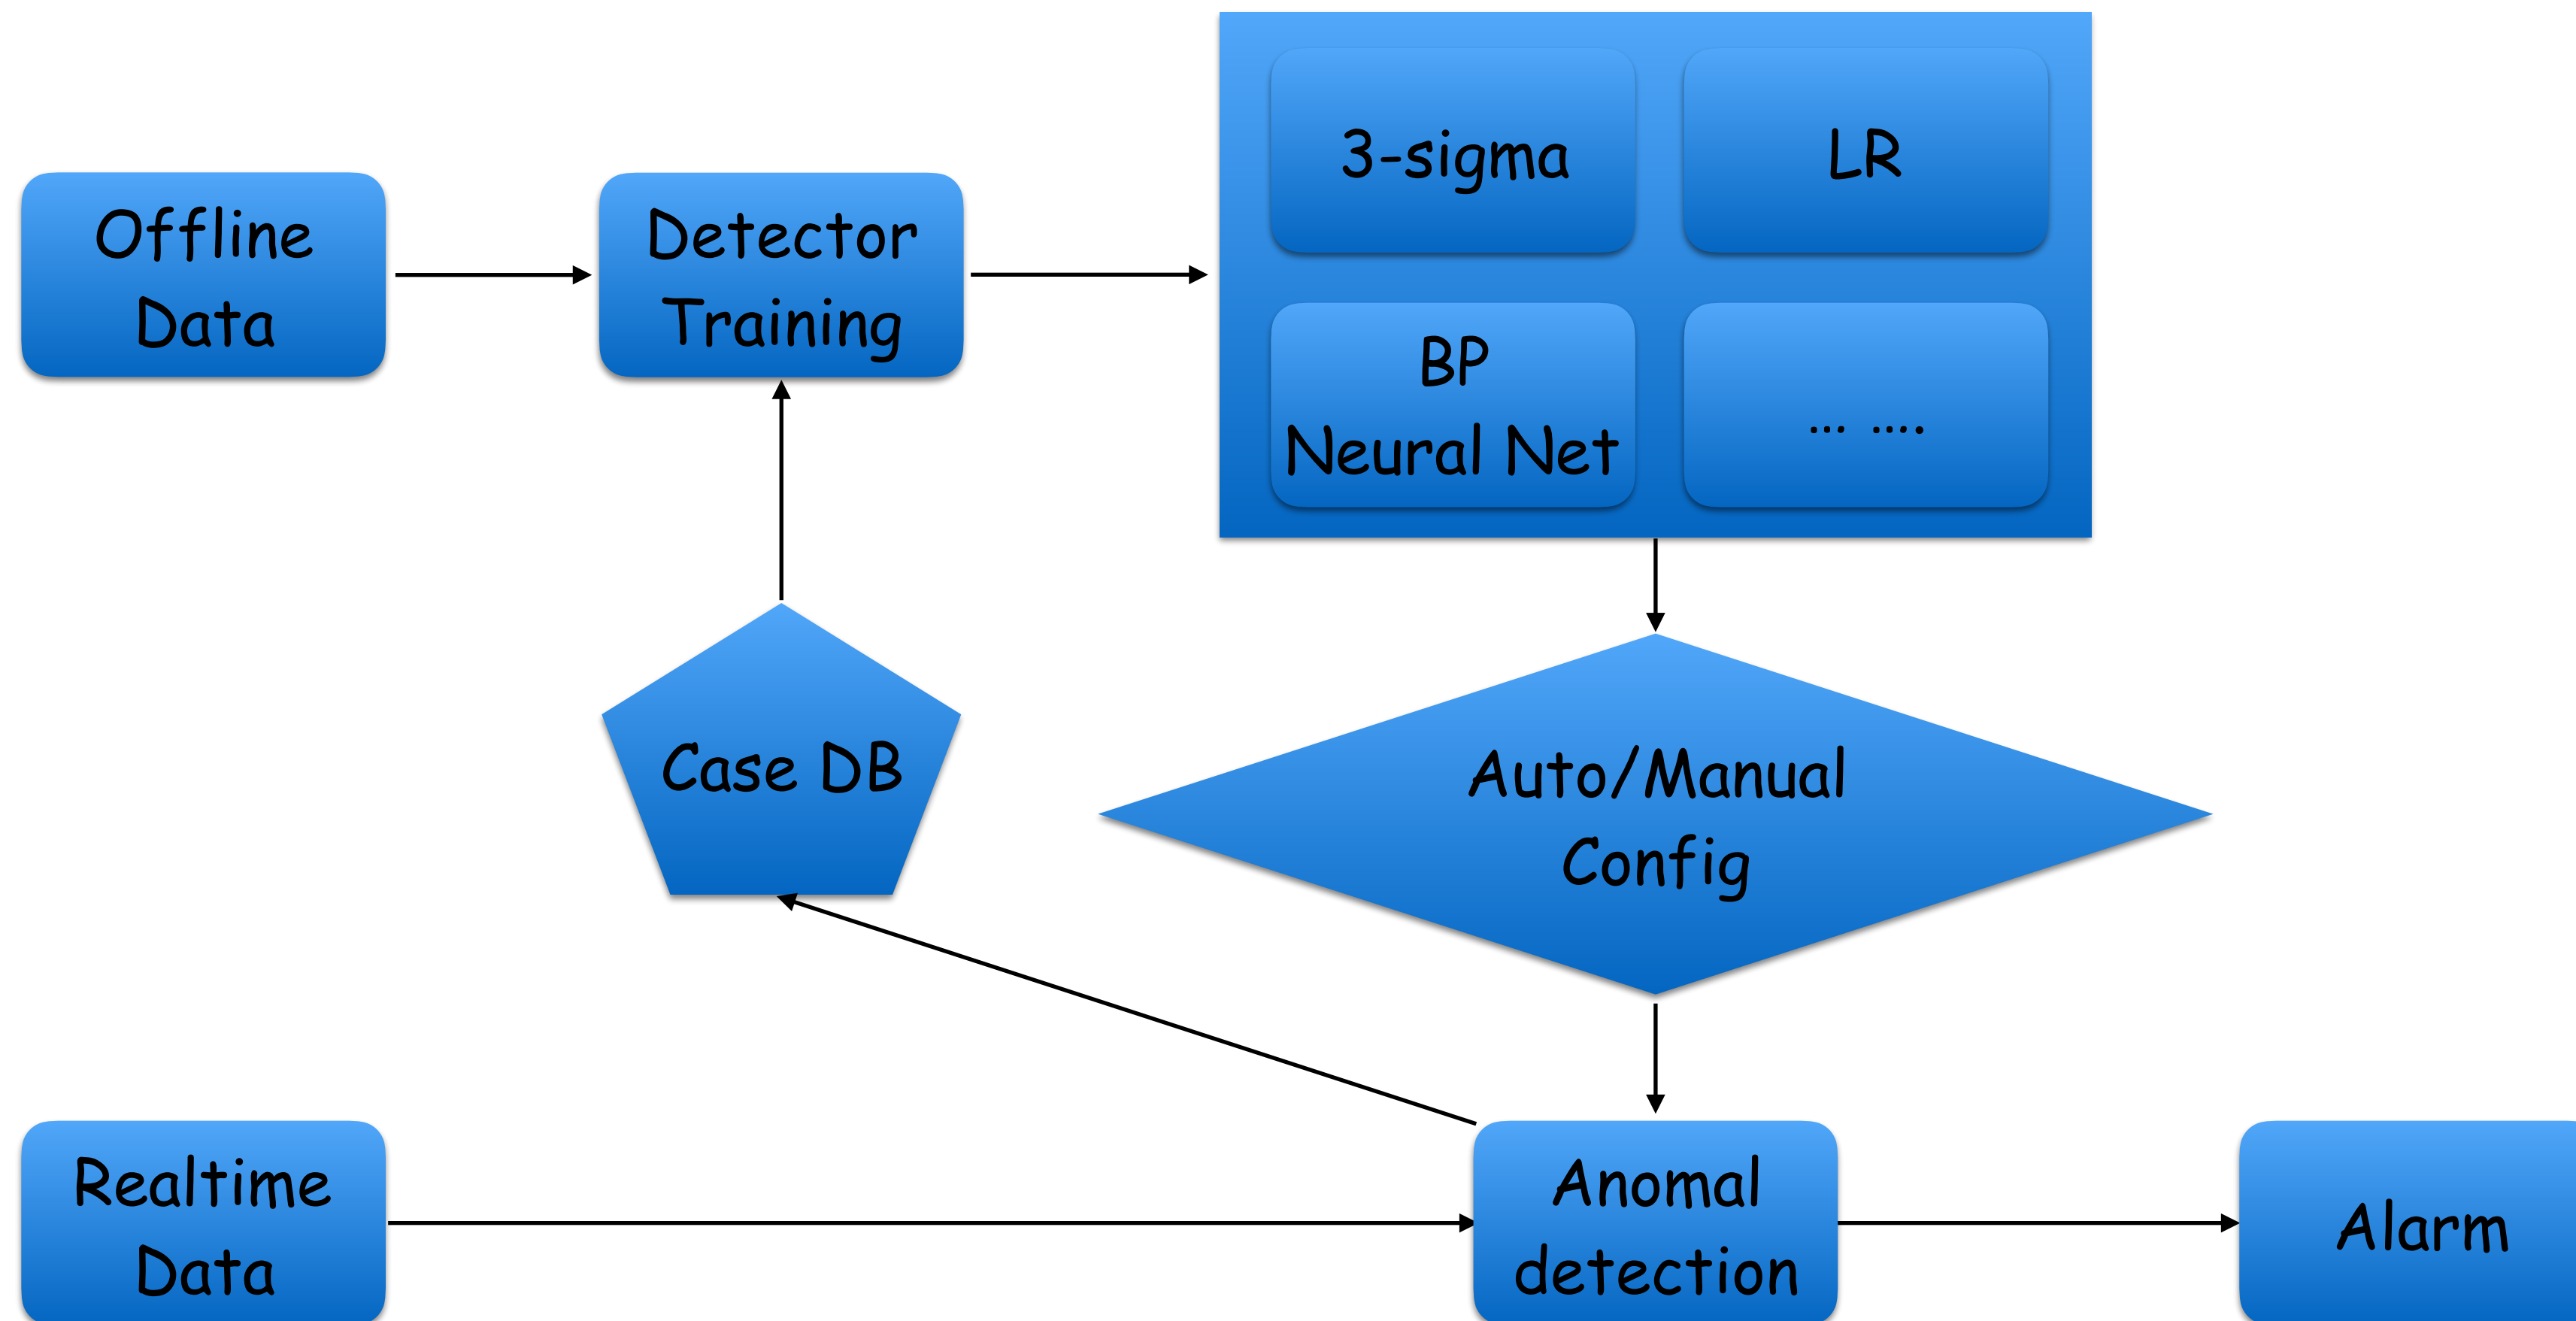

- Other SREs have needs to customize the existed algorithms
- Codes are hard to reuse
  - ✓ Different execution environments (programming languages)
  - ✓ Different data sources with different formats
  - ✓ Different teams/projects

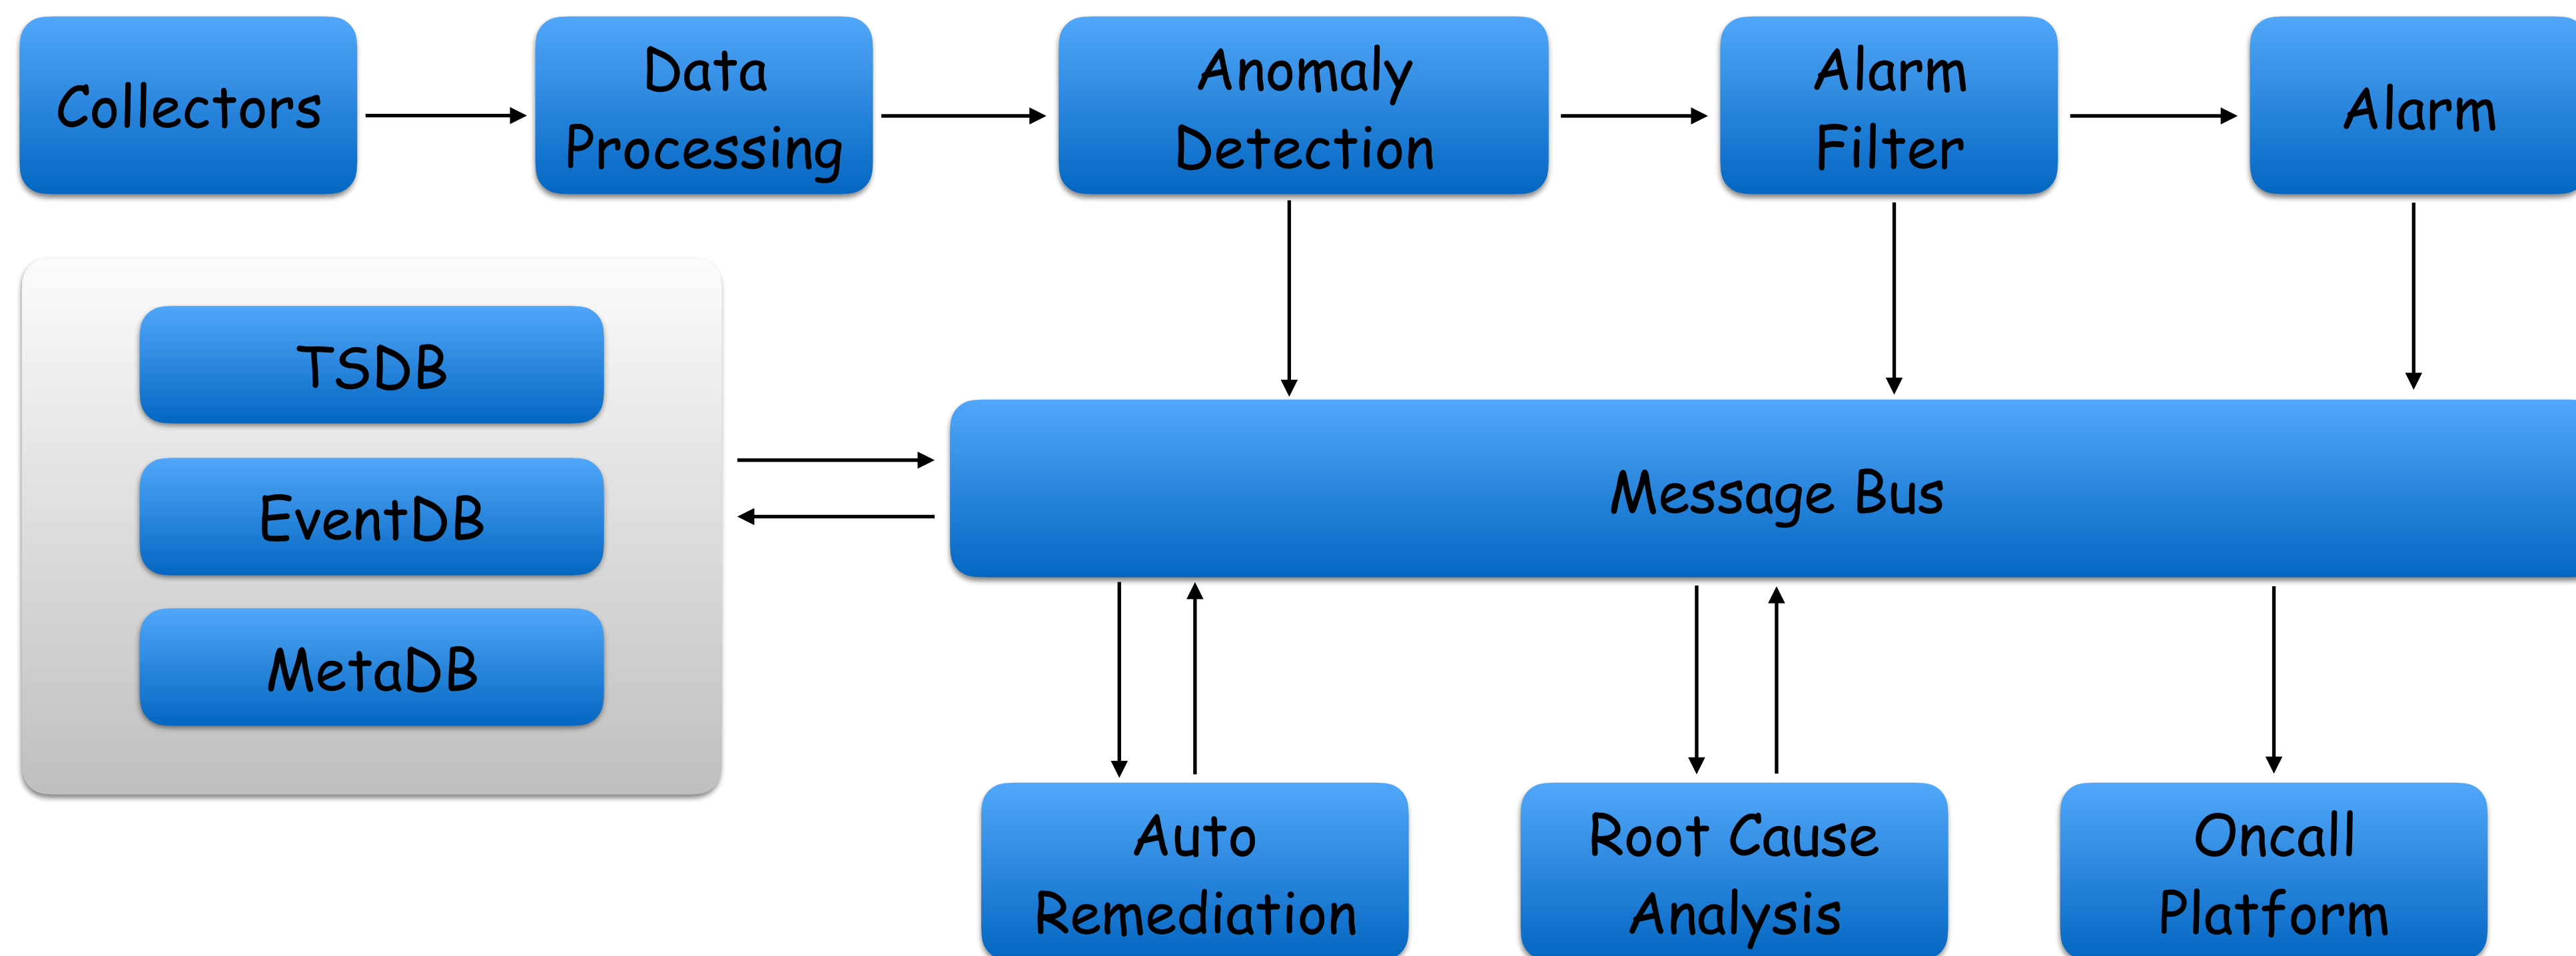

# ARK – A Generalized OP Platform

# Unified Algorithms and deployment

# Unified Monitoring DB and Platform

## 地图活动直播间10.1
